

$\lambda = h/mv$, where
 λ is wavelength in m,
 h is Planck's constant ($6.626 \times 10^{-34} \text{ J}\cdot\text{s}$),
 m is mass in kg,

m_p - the mass of proton

m_n - the mass of neutron

m_e - the mass of electron

$m_{\alpha,p}$ - the mass of alpha part

v is speed in m/s.

To complete this problem you must convert your wavelength to meters and your mass to kilograms.

$$\lambda = 750.0 \text{ nm} (1 \text{ m}) / (1 \times 10^9 \text{ nm}) = 7.5 \times 10^{-7} \text{ m}$$
$$m_p = 1.673 \times 10^{-24} \text{ g} (1 \text{ kg}) / (1000 \text{ g}) = 1.673 \times 10^{-27} \text{ kg}$$

Rearrange the equation and solve for speed.

$$v = h/m\lambda = (6.626 \times 10^{-34} \text{ J}\cdot\text{s}) / (1.673 \times 10^{-27} \text{ kg})(7.5 \times 10^{-7} \text{ m}) = 0.528 \text{ m/s}$$

$$m_n = 1.675 \times 10^{-24} \text{ g} (1 \text{ kg}) / (1000 \text{ g}) = 1.675 \times 10^{-27} \text{ kg}$$
$$v = h/m\lambda = (6.626 \times 10^{-34} \text{ J}\cdot\text{s}) / (1.675 \times 10^{-27} \text{ kg})(7.5 \times 10^{-7} \text{ m}) = 0.527 \text{ m/s}$$

$$m_e = 9.109 \times 10^{-28} \text{ g} (1 \text{ kg}) / (1000 \text{ g}) = 9.109 \times 10^{-31} \text{ kg}$$
$$v = h/m\lambda = (6.626 \times 10^{-34} \text{ J}\cdot\text{s}) / (9.109 \times 10^{-31} \text{ kg})(7.5 \times 10^{-7} \text{ m}) = 969.9 \text{ m/s}$$
$$m_{\alpha,p} = 6.645 \times 10^{-24} \text{ g} (1 \text{ kg}) / (1000 \text{ g}) = 6.645 \times 10^{-27} \text{ kg}$$
$$v = h/m\lambda = (6.626 \times 10^{-34} \text{ J}\cdot\text{s}) / (6.645 \times 10^{-27} \text{ kg})(7.5 \times 10^{-7} \text{ m}) = 0.133 \text{ m/s}$$
