

Answer on Question #55230 - Chemistry - General chemistry

Question:

A student performs the following gravimetric analysis of iron ions in a water system: $\text{Fe}^{2+}(\text{aq}) + 2\text{CO}_3^{2-}(\text{aq}) = \text{FeCO}_3(\text{s})$ If this student used excess carbonate and obtained the following data, what was the original concentration in moles/L of Fe^{2+} in the water sample? Total Volume of Solution: 100.00 mL Mass of FeCO_3 collected: 23.758 grams. Is this how you would solve it change 100 ml to .1 liters. $115.853x = 23.758 \times .1 = .02$ liters

Answer:

Not actually.

First of all in this calculation you have to pay significant attention to significant figures.

When you are transforming units, the result is as following

$$100.00 \text{ mL} = 0.10000 \text{ L (5 significant figures)}$$

$$m = 23.758 \text{ g (5 significant figures)}$$

You have to use the scientific way of thinking — calculate the quantity of substance and then concentration

$$n(\text{Fe}^{2+}) = n(\text{FeCO}_3) = m(\text{FeCO}_3)/M_w(\text{FeCO}_3)$$

$$M_w(\text{FeCO}_3) = 115.8539 \text{ (7 significant figures)}$$

$$n(\text{Fe}^{2+}) = 23.758/115.8538 = 0.20507 \text{ moles (5 significant figures)}$$

$$c(\text{Fe}^{2+}) = n(\text{Fe}^{2+})/V = 0.20507/0.10000 = 2.0507 \text{ moles/L (5 significant figures)}$$
