Answer on Question \#41034 - Economics - Economics of enterprise

A purely competitive wheat farmer can sell any wheat he grows for $\$ 30$ per bushel. His five acres of land show diminishing returns, because some are better suited for wheat production than others. The first acre can produce 1000 bushels of wheat, the second acre 900 , the third 800 , and so on.

1) How many bushels will each of the farmer's five acres produce?
Acre Quantity Total quantity Revenue per acre TR MR
1 acre 1000 bushels $1000 \quad 30,000 \quad 30,000-$
2 acre 900 bushels $1900 \quad 27,000 \quad 57,000 \quad 30$
3 acre 800 bushels $2700 \quad 24,000 \quad 81,000 \quad 30$
4 acre 700 bushels $3400 \quad 21,000 \quad 102,000 \quad 30$
5 acre 600 bushels $4000 \quad 18,000 \quad 120,000 \quad 30$
2) How much revenue will each acre generate?

Revenue per acre $=\mathrm{P}^{*} \mathrm{Q}, \mathrm{P}=\$ 30$
3) What are the TR and MR for each acre?
$\mathrm{TR}=\mathrm{Q} *$ Revenue per acre
$\mathrm{MR}=(\mathrm{TR} 2-\mathrm{TR} 1) /(\mathrm{Q} 2-\mathrm{Q} 1)=\mathrm{P}=\$ 30$
