

### Question 32258

Since the rocket rises with constant acceleration, directed upwards, the velocity at given moment of time is  $v(t) = at$ .

a) The y-coordinate of the rocket as a function of time is  $y(t) = \frac{at^2}{2}$ . Hence, for given  $y$ , time to move to it is  $t_1 = \sqrt{2 \frac{y}{a}}$ . Thus, according to first formula, at that moment of time velocity is

$v = at_1 = a \sqrt{\frac{2y}{a}} = \sqrt{2ya}$ . This relation connects velocity with height and acceleration. Knowing that

for  $h = 3.3 \text{ m}$  velocity is  $v = 28 \frac{\text{m}}{\text{s}}$ , obtain  $a = \frac{v^2}{2h} = 118.8 \frac{\text{m}}{\text{s}^2}$ .

b) Since  $y(t) = \frac{at^2}{2}$ , for  $t = 0.1 \text{ s}$ ,  $y = 118.8 \cdot \frac{(0.1)^2}{2} = 0.594 \text{ m}$ .

c) Knowing that  $v(t) = at$ , for  $t = 0.1 \text{ s}$ ,  $v = 118.8 \cdot 0.1 = 11.88 \frac{\text{m}}{\text{s}}$ .
