

### Answer on Question#37649, Physics, Other

#### Question:

A fountain sends a stream of water straight up into the air to a maximum height of 4.33 m. The effective area of the pipe feeding the fountain is  $5.82 \times 10^{-4} \text{ m}^2$ . Neglecting air resistance and any viscous effects, determine how many gallons per minute are being used by the fountain. (1 gal =  $3.79 \times 10^{-3} \text{ m}^3$ )

#### Answer:

$T + U = \text{const}$  - the law of conservation of energy;

$T$  - kinetic energy of water,

$U$  - potential energy of water,

$$T = \frac{mv^2}{2}$$

$$U = mgh$$

$h$  - maximum height,

$m$  - mass,  $v$  - speed.

In our case: 
$$0 + mgh = \frac{mv_0^2}{2} + 0$$

Therefore, initial velocity of water equals: 
$$v_0 = \sqrt{2gh} = 9.21 \frac{\text{m}}{\text{s}}$$

Volume of the water equals: 
$$V = Av_0t$$

$A$  - effective area of the pipe,  $t$  - time.

Full volume per 1 minute equals: 
$$V = 9.21 \frac{\text{m}}{\text{s}} 5.82 * 10^{-4} \text{ m}^2 * 60 \text{ s} = 0.322 \text{ m}^3$$

Full volume in gallons: 
$$V = \frac{0.322}{3.79 * 10^{-3}} = 85 \text{ gallons}$$

Answer: 85 gallons
