

- $p$  is the hydrostatic pressure ( $\text{Pa} = 1 \text{ kg}/(\text{m}\cdot\text{s}^2)$ ),
- $d$  is the fluid density ( $\text{kg}/\text{m}^3$ ),
- $g$  is gravitational acceleration ( $\text{m}/\text{s}^2$ ),

$h$  is height of liquid column (m).

$$p = d^\alpha g^\beta h^\gamma \gg \text{kg} * \text{m}^{-1} * \text{s}^{-2} = \text{kg}^\alpha \text{m}^{-3\alpha} \text{m}^\beta \text{s}^{-2\beta} \text{m}^\gamma \gg$$

$$\gg \alpha = 1, -3\alpha + \beta + \gamma = -1, -2\beta = -2 \gg \alpha = 1, \beta = 1, \gamma = 1$$

That's why:

$$p = dgh$$
