

Answer on question #58698, Physics / Astronomy | Astrophysics

How long will a  $5M_{\odot}$  star burn hydrogen as fuel, given that the Sun will do so for about  $10^{10}$  years?

**Solution:**

Star's lifetime equals to  $t = \frac{E_{released}}{L}$ , where  $E_{released}$  - energy released after all hydrogen fusion into helium,  $L$  - star luminosity.

Solar luminosity equals to  $3.828 \cdot 10^{33} \text{ erg/s}$ . For the star with  $M=5M_{\odot}$  the released amount of energy will be proportional to the mass, i.e.

$$5 \cdot E_{released} = 5 \cdot 10^{10} y \cdot 31556926 \frac{s}{y} \cdot 3.828 \cdot 10^{33} \frac{\text{erg}}{s} = 5 \cdot 1.21 \cdot 10^{51} \text{ erg} .$$

The increasing of mass leads to the increase of luminosity which is roughly proportional to  $\frac{L}{L_{\odot}} = \left(\frac{M}{M_{\odot}}\right)^{\alpha}$ , where  $\alpha \approx 3.9$

$$\frac{L}{L_{\odot}} = 5^{3.9} \approx 532.$$

Then  $L = 532 * L_{\odot} = 532 \cdot 3.828 \cdot 10^{33} \text{ erg/s}$

The final expression as follows

$$t = \frac{5 \cdot 1.21 \cdot 10^{51} \text{ erg}}{532 \cdot 3.828 \cdot 10^{33} \text{ erg/s}} = 9.4 \cdot 10^7 \text{ y}$$

Answer: the star will burn its fuel in  $9.4 \cdot 10^7 \text{ y}$
