## Answer on Question \#63131, Physics / Mechanics

A hovering mosquito is hit by a raindrop that is 30 times as massive and falling at $8.1 \mathrm{~m} / \mathrm{s}, \mathrm{a}$ typical raindrop speed. How fast is the raindrop, with the attached mosquito, falling immediately afterward if the collision is perfectly inelastic?

## Solution

According to the conservation of momentum,

$$
\begin{aligned}
& m_{m} v_{m}+m_{d} v_{d}=\left(m_{m}+m_{d}\right) v ; \\
& v=\frac{m_{m} v_{m}+m_{d} v_{d}}{\left(m_{m}+m_{d}\right)} ; \\
& v=\frac{m \times 0+(30 m) \times 8.1}{(m+30 m)}=\frac{243 m}{31 m}=7.84 \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

Answer: $7.84 \mathrm{~m} / \mathrm{s}$.
