## Answer on Question \#63350, Physics / Other

Why can't you report an experimental value for pi to 10 digits?

## Solution:

Since experimental methods for measuring PI are quite rude. They depend on the accuracy of the conducted measurements.
As an example one of the methods:

## Measurement by weighing

On a piece of cardboard, draw the square. Inscribe him in a circle. Cut out a square. Determine the mass of the cardboard square with the help of school weights. Cut out a square from a circle. Weigh and him. Knowing the weight of square $\mathrm{m}_{\text {sq }}(=10 \mathrm{~g})$ and the inscribed circle $\mathrm{m}_{\text {cir }}(=$ 7.8 g ) use the formulas

$$
\begin{aligned}
& m=\rho V \\
& V=S h
\end{aligned}
$$

where p and h are respectively the density and thickness of the cardboard, S - area of the figure.

Consider the equation:

$$
\begin{gathered}
m_{s q}=\rho S h=\rho 4 R^{2} h \\
m_{\text {cir }}=\rho R^{2} h
\end{gathered}
$$

here

$$
\begin{gathered}
m_{\mathrm{cir}} / \mathrm{m}_{\mathrm{sq}}=\rho \mathrm{R}^{2} \mathrm{~h} / \rho 4 \mathrm{R}^{2} \mathrm{~h}=\pi / 4 \\
\pi=4 \mathrm{~m}_{\mathrm{cir}} / \mathrm{m}_{\mathrm{sq}}=4 * 7.8 / 10=3.12
\end{gathered}
$$

Naturally, in this case, an approximate value depends on the accuracy of weighing sizes and shapes.
